

Autonomous arXiv Paper Digest & QA Agent

1. Background & Goal

Researchers and engineers spend a lot of time skimming arXiv papers to decide what's worth a deep read. Your task is to build an **agent** that takes a topic or a specific arXiv paper ID, fetches the paper(s), reads them, and produces a structured executive briefing — plus lets a user ask follow-up questions about the paper's content.

This assessment evaluates how you think about **agent/state design, retrieval, and pragmatic engineering under ambiguity** — not whether you can memorize a framework's API. There is no single "correct" architecture. We care about your reasoning, tradeoffs, and code quality more than the choice of any specific library.

2. What the Agent Should Do

Input

One of:

- A natural-language research topic (e.g., *"recent work on KV-cache compression for LLMs"*)
- A specific arXiv ID or URL (e.g., 2401.12345 or <https://arxiv.org/abs/2401.12345>)

Core Pipeline (Agentic State Graph)

Design this as an explicit **stateful graph** (nodes + edges + shared state), not a single monolithic prompt. Suggested stages — feel free to adjust, merge, or add nodes as long as the flow is coherent and justified:

1. **Query Understanding** — parse intent: topic search vs. specific paper lookup.
2. **arXiv Retrieval** — call the arXiv API to find candidate paper(s) (metadata: title, authors, abstract, PDF link, categories, date).
3. **Selection/Ranking** (if topic search) — pick the most relevant paper(s) from results.
4. **Fetch & Parse** — download the PDF and extract text (sections, abstract, references at minimum).
5. **Chunk & Embed** — chunk the parsed text and store embeddings in a vector DB for later QA.
6. **Summarize** — generate a structured executive briefing.
7. **QA Loop** — accept follow-up questions from the user, retrieve relevant chunks from the vector DB, and answer with grounding in the paper (i.e., basic RAG).

The graph should have identifiable **state** that persists across nodes (e.g., paper metadata, parsed text, chunk store reference, conversation history for QA) and should handle at least one realistic failure case gracefully (see §5).

Output: Executive Briefing

A structured artifact (JSON or Markdown) containing, at minimum:

- Title, authors, arXiv ID, publish date, link
- 1-paragraph plain-English summary ("why this paper matters")
- Problem statement
- Method/approach (bullet points)
- Key results / claims
- Limitations (explicit — don't let the model skip this)
- Suggested follow-up questions a reader might ask

QA Mode

After the briefing is generated, the user can ask free-form questions about the paper. Answers must be **grounded in retrieved chunks** (RAG). If the answer isn't in the paper, the agent should say so rather than hallucinate.

3. Deliverables

1. **Working code** in a public GitHub repo (or zip), with clear setup instructions.
 2. **README** including:
 - Architecture diagram or description of your state graph (nodes, edges, state shape)
 - Setup & run instructions (must run locally with free/open-source tools or any platform of your choice(any support is not given by us regarding this))
 - Example run (input → briefing output → 2–3 sample QA exchanges), pasted or as a screen recording/gif
 - A short "Design Decisions & Tradeoffs" section (½–1 page): what you chose, what you'd do differently with more time, known limitations
 3. **A short Video reflection (4 Min)- we stop seeing your video after 4 min** : on the approach you have taken to complete this assement.
-

4. Constraints

- **All tools/libraries can be any open-source or free-tier usable or any usable paid ones you already have.** Examples (not mandatory — pick your own stack):
 - Orchestration: LangGraph, LlamaIndex Workflows, custom Python state machine, Haystack, CrewAI, etc.
 - LLM: any free-tier API (e.g., Groq, Google AI Studio/Gemini free tier, OpenRouter free models) or a local open-weight model (Ollama + Llama/Mistral/Qwen, etc.)

- Vector DB: you can use a **local vector DB** — no need for a cloud-hosted vector DB. Examples: Chroma, FAISS, Qdrant (local mode), LanceDB, Weaviate (embedded), etc.
 - PDF parsing: PyMuPDF, pdfplumber, `arxiv` Python package, unstructured.io (OSS mode), etc.
 - arXiv access: the official [arXiv API](#) (Atom feed) — no scraping required
 - No paid API keys should be required to run your submission. If you use a hosted LLM, use a free tier and document any rate limits we should be aware of when testing.
 - Feel happy to use any AI assistance that you already have, but be mindful of the code you are submitting- we would ask you clarification on certain decision that you made while building the project.
 - Language: Python preferred.
-

5. Things We Want You to Think About (not all required — use judgement)

- What happens when arXiv returns zero or many candidate papers for a vague topic?
 - What happens if the PDF fails to parse cleanly (scanned images, broken layout, huge paper)?
 - How do you keep the QA loop's answers grounded rather than hallucinated?
 - How does state get passed/persisted between the summarization stage and the QA stage — is it in-memory, a session object, a DB?
-

6. Evaluation Rubric

Area	What we're looking for	Weight
Agent/graph design	Clear, justified state graph; not just a single prompt chain	25%
Correctness & grounding	Briefing is accurate; QA answers are grounded in retrieved content, not hallucinated	25%
Retrieval & parsing quality	Sensible chunking strategy, working vector search, reasonable arXiv query handling	20%
Code quality	Readable, modular, reasonable error handling	15%
Communication	README clarity, design tradeoffs section, reflection	15%

We are explicitly **not** grading on UI polish. A CLI or simple script-based interaction is completely fine.

7. Out of Scope (don't build these)

- A frontend/UI beyond a basic CLI or notebook interface
 - Multi-user auth, deployment, or production infra
 - Support for non-arXiv sources
 - Fine-tuning any models
-

8. Submission

- Link to your github repo or zip file + README
- Time-box yourself to roughly 2 - 3 days; we'd rather see a smaller, well-reasoned system than a sprawling half-working one. If you run out of time, tell us in the README what you'd have done next.
